## 1 Polynomial Rings

- Reading: Gallian Ch. 16
- Def: Let $R$ be a commutative ring with unity. The ring of polynomials over $R$ is the ring $R[x]$ consisting of all expressions of the form $a_{0}+a_{1} x+a_{2} x^{2}+\cdots$, where each $a_{i} \in R$ and all but finitely many $a_{i}$ 's are zero. (We usually omit the zero terms, so $1+5 x+10 x^{2}+3 x^{3}$ is shorthand for $1+5 x+10 x^{2}+3 x^{3}+0 x^{4}+0 x^{5}+\cdots$.)
For two polynomials $p(x)=\sum_{i} a_{i} x^{i}$ and $q(x)=\sum_{i} b_{i} x^{i}$, their $\operatorname{sum}(p+q)(x)$ is defined to be the polynomial $\sum_{i}\left(a_{i}+b_{i}\right) x^{i}$ and their $\operatorname{product}(p q)(x)$ is the polynomial $\sum_{i}\left(\sum_{j=0}^{i}\left(a_{j} b_{j-i}\right)\right) x^{i}$, where $a_{i}+b_{i}$ and $a_{j} b_{j-i}$ are defined using the operations of $R$.
- Def: The degree $\operatorname{deg}(p)$ of a nonzero polynomial $p(x)=\sum_{i} a_{i} x^{i}$ is the largest $d$ such that $a_{d} \neq 0 . a_{d}$ is called the leading coefficient of $p . p$ is called monic if $a_{d}=1$.
- Examples: $p(x)=3 x^{2}+4 x+1$ and $q(x)=5 x+6$ in $\mathbb{Z}_{7}[x]$.

## - Remarks:

$-R[x]$ is a commutative ring with unity.

- Two different polynomials can define the same function on $R$, but we still treat them as different elements of $R[x]$. For example $p(x)=x \cdot(x-1) \cdots(x-p+1)$ defines the zero function on $\mathbb{Z}_{p}$, but is not the zero polynomial (why?).
- For polynomials of degree at most $n$, their sum can be computed using $n$ operations over $R$ and their product using $O\left(n^{2}\right)$ operations over $R$. (Best known multiplication algorithm uses $O(n \log n)$ operations.) Note similarity with sum and product of integers!
- Thm 16.1: $R$ an integral domain $\Rightarrow R[x]$ an integral domain. Proof:
- We will focus on the case that the coefficient ring $R$ is a field $F$. In this case, we will see that the ring $F[x]$ has many similar properties to the ring $\mathbb{Z}$. In fact, things tend to be easier to prove and to compute over $F[x]$ than over $\mathbb{Z}$.
- Division with Remainder (Thm 16.2): $f(x), g(x) \in F[x], g(x)$ nonzero, then there exist (unique) polynomials $q(x)$ and $r(x)$ with $\operatorname{deg}(r)<\operatorname{deg}(g)$ and $f(x)=q(x) g(x)+r(x)$. Moreover, if $f$ and $g$ have degree at most $n$, then $q(x)$ and $r(x)$ can be computed using $O\left(n^{2}\right)$ operations from $F$.

Proof and algorithm (long division of polynomials): Inputs are $f(x)=a_{n} x^{n}+$ $a_{n-1} x^{n-1}+\cdots+a_{1} x+a_{0}, g(x)=b_{m} x^{m}+b_{m-1} x^{m-1}+\cdots+b_{1} x+b_{0}$. We'll compute $q(x)=c_{n-m} x^{n-m}+\cdots+c_{1} x+c_{0}$.

1. Let $f_{0}(x)=f(x)$.
2. For $i=0$ to $n-m$ :
(a) Let $a$ be the coefficient of $x^{n-i}$ in $f_{i}(x)$, and let $c_{n-m-i}=b_{m}^{-1} a$.
(b) Let $f_{i+1}(x)=f_{i}(x)-c_{n-m-i} x^{n-m-i} \cdot g(x)$. (This zeroes out the term of degree $n-i$.)
3. Output $q(x)=c_{n-m} x^{n-m}+\cdots+c_{1} x+c_{0}$.

- Example: $f(x)=3 x^{2}+4 x+1$ divided by $g(x)=5 x+6$ in $\mathbb{Z}_{7}[x]$.
- Note: all we used about $F$ being a field is that $b_{m}$ has an inverse. Over general rings $R$, division is possible if the leading coefficient of $g(x)$ is a unit (e.g. if $g$ is monic).
- Corollary: Let $R$ be a commutative ring with unity, $f(x) \in R[x]$, and $a \in R$. Then $f(a)=0$ if and only if $(x-a)$ divides $f(x)$ in $R[x]$.
Proof:
- Corollary: A polynomial of degree $n$ over an integral domain $R$ has at most $n$ zeroes.
- This simple fact is extremely useful! Ought to be called the "fundamental thm of algebra" (which is unfortunately used for the fact that every polynomial has a root in $\mathbb{C}$ ).
- Another example of "If an algebraic identity fails, then it fails often."

## Proof:
