1	Agenda	1
2	Hierarchy Theorems, Continued	1
3	Space Complexity Classes	2
4	Nondeterminism	2

1 Agenda

- Space and Nondeterministic complexity classes
- Nondeterministic hierarchy theorem
- Relating time, space, and nondeterminism
- Reductions and completeness

2 Hierarchy Theorems, Continued

Theorem 1 (Almost everywhere hierarchy) *If f is a proper complexity function, there exists a language $L \in \mathbf{TIME}(2^{O(n)}f(n)^2)$ such that any M with $\mathcal{L}(M) = L$ (i.e. with no errors) takes time $> f(n)$ almost everywhere (i.e. L is “hard” a.e.).*

Last time we constructed L , but we didn’t verify $L \in \mathbf{TIME}(2^{O(n)}f(n)^2)$. Where does the exponential factor come from? To decide L on input x , recall that we needed to look at all strings $y \leq x$ (lexicographically). Fully verifying the time bound is left as an exercise.

Corollary 2 *There exists a language $L \in \mathbf{EXP}(= \mathbf{TIME}(2^{n^{O(1)}}))$ such that deciding L takes time $> 2^n$ a.e.*

Another form of “ L is hard often” introduces the notion of “average-case complexity”: $\forall M$ running in time $f(n)$, the fraction of inputs on which $M(x) \neq \chi_L(x)$ is at least a constant δ asymptotically as $n \rightarrow \infty$. Noting that the all-1 or all-0 TM is correct 50% of the time asymptotically, we could ideally hope to have δ to be something like 49%.

3 Space Complexity Classes

Definition 3 $\text{SPACE}(f(n))$ is the set of languages decidable by a TM in space $f(n)$.

Recall that “space” refers only to workspace, which does not include the input and output.

Definition 4 (“Log space”) $\mathbf{L} = \bigcup_c \text{SPACE}(c \log n)$.

Definition 5 (“Polynomial space”) $\mathbf{PSPACE} = \bigcup_c \text{SPACE}(n^c)$.

Log space is the smallest complexity class we will study in this course. Constant space can be hardwired into the finite state control of a TM (i.e. $\text{SPACE}(O(1)) = \text{SPACE}(0)$). In fact:

Remark 6 $\text{SPACE}(\log \log n) = \text{SPACE}(O(1)) = \text{SPACE}(0) = \{\text{regular languages}\}$.

Notice that $\log n$ bits are needed even to keep a pointer in the input or to calculate the size of the input. \mathbf{L} is thus a good measure of feasible computation for massive data sets: with it one can keep track of a constant number of pointers, but cannot do too much more.

The following operations are typical of problems in \mathbf{L} : addition (trivial to prove this), multiplication (on problem set 1), and division (difficult—solved in 2001).

On the other hand, \mathbf{PSPACE} is much more powerful; typical problems are games (e.g. does player 1 have a winning strategy from a given position in some game?), such as go, chess, and geography.

On problem set 1, we will see that there is a hierarchy theorem for space. A corollary to this theorem is:

Corollary 7 $\mathbf{L} \neq \mathbf{PSPACE}$.

4 Nondeterminism

Recall that a nondeterministic TM (NTM) is just like a deterministic TM except that at any time step there can be several options for the possible next states, what it writes, and so on, such that the transition function becomes a transition relation. Thus on a given input, there can be many different possible computations, corresponding to all possible nondeterministic choices.

Definition 8 An NTM M accepts x if there exists a computation of M on x that halts and outputs 1. Similarly, its language $\mathcal{L}(M) = \{x : \exists \text{ computation of } M \text{ on } x \text{ that halts and outputs } 1.\}$ (i.e. “guess and verify”).

The running time of an NTM on x is the maximum running time used on input x over all computations, even those that do not output 1, and is denoted $\mathbf{NTIME}(f(n))$. The space used on x is the maximum workspace used on x over all computations, and is denoted $\mathbf{NSPACE}(f(n))$. Note that if the NTM doesn’t halt on a certain set of choices, it can be redefined by limiting all computations to a particular running time. Analogous to the deterministic class we define $\mathbf{NP} \stackrel{\text{def}}{=} \bigcup_c \mathbf{NTIME}(n^c)$, $\mathbf{NEXP} = \bigcup_c \mathbf{NTIME}(2^{n^c})$, $\mathbf{NL} = \bigcup_c \mathbf{NSPACE}(c \log n)$, and $\mathbf{NPSPACE} = \bigcup_c \mathbf{NSPACE}(2^{n^c})$.

Nondeterminism is not a realistic/physical resource. Then why study it? It turns out that it captures many important computational problems, and helps us understand more realistic resources, such as **TIME** and **SPACE**.

Recall an alternate characterization of **NP**:

Proposition 9 $L \in \mathbf{NP}$ iff there exists a relation $R \subset \Sigma^* \times \Sigma^*$ such that

- (1) $x \in L$ iff $\exists y$ such that $(x, y) \in R$ (y is called a “witness” for x),
- (2) deciding R is in **P** (“polynomially decidable”), and
- (3) \exists fixed polynomial p such that if $(x, y) \in R$ then $|y| \leq p(|x|)$ (“polynomially balanced”).

Proof: \Leftarrow : The nondeterministic choices allow witnesses (of polynomial length) to be guessed, and $(x, y) \in R$ can be checked in polynomial time.

\Rightarrow : (Sketch) Define R such that witnesses y correspond to the sequence of nondeterministic choices of the NTM M deciding L and $R(x, y) = 1$ if $M(x)$ accepts with nondeterministic choices y . ■

4.1 Examples of Problems in NP

- $\text{SAT} = \{\varphi(x_1, \dots, x_n) : \varphi \text{ is a propositional formula such that } \exists a = (a_1, \dots, a_n) \in \{0, 1\}^n \text{ with } \varphi(a) = 1\}$. (Note: φ can be evaluated in polynomial time on a given assignment, so such a witness is checkable in polynomial time.)
- $\text{CLIQUE} = \{(G, k) : \text{graph } G \text{ has complete subgraph on } k \text{ vertices}\}$. (Note: The completeness of the witness, a complete subgraph if it exists, is checkable in polynomial time.)
- $\text{GRAPH-ISOMORPHISM} = \{(G_1, G_2) : G_1 \text{ is the “same” as } G_2 \text{ up to relabeling}\}$.
- $\text{SHORT-PROOF} = \{(\varphi, 1^n) : \varphi \text{ is a mathematical theorem with a proof of length } \leq n\}$. (Note: The proof and theorem are in ZFC set theory, say.)

4.2 Consequences of $\mathbf{P}=\mathbf{NP}$

- Mathematicians can be replaced by algorithms (pointed out in a letter from Gödel to von Neumann in 1955).
- All reasonable search problems can be solved efficiently, which would make Artificial Intelligence and computational learning dramatically easier.
- All optimization problems (such as chip designs to minimize power usage) can be solved efficiently.
- Cryptography falls apart, since schemes become easier to break.
- Randomized algorithms are not substantially more efficient than deterministic ones.

Determining whether $\mathbf{P} = \mathbf{NP}$ is viewed as one of the most important questions in math and science, and as a testament it is one of the million-dollar questions sponsored by the Clay Institute of Mathematics.
